LocalSolver

Math programming by local search

A solver aligned with enterprise needs

- Provides high-quality solutions in seconds
- Scalable: to tackle problems with millions of decisions
- Proves optimality when possible (best effort)

A solver aligned with practitioner needs

- « Model & Run »
 - Simple mathematical modeling formalism
 - Direct resolution: no need of complex tuning
- A simple and transparent pricing

LocalSolver

A new-generation solver

- Computing good-quality solutions by local search
- Computing lower bounds separately (relaxation, inference, cuts)

A quality software

- An innovative modeling language for fast prototyping
- Lightweight object-oriented APIs: a few classes only
- Reliable and robust: quality assurance through continuous integration
- Fully portable: Windows, Linux, Mac OS (x86, x64)
- Reactive support, realized by developers themselves (even for academics)

Why local search?

Weaknesses of tree search

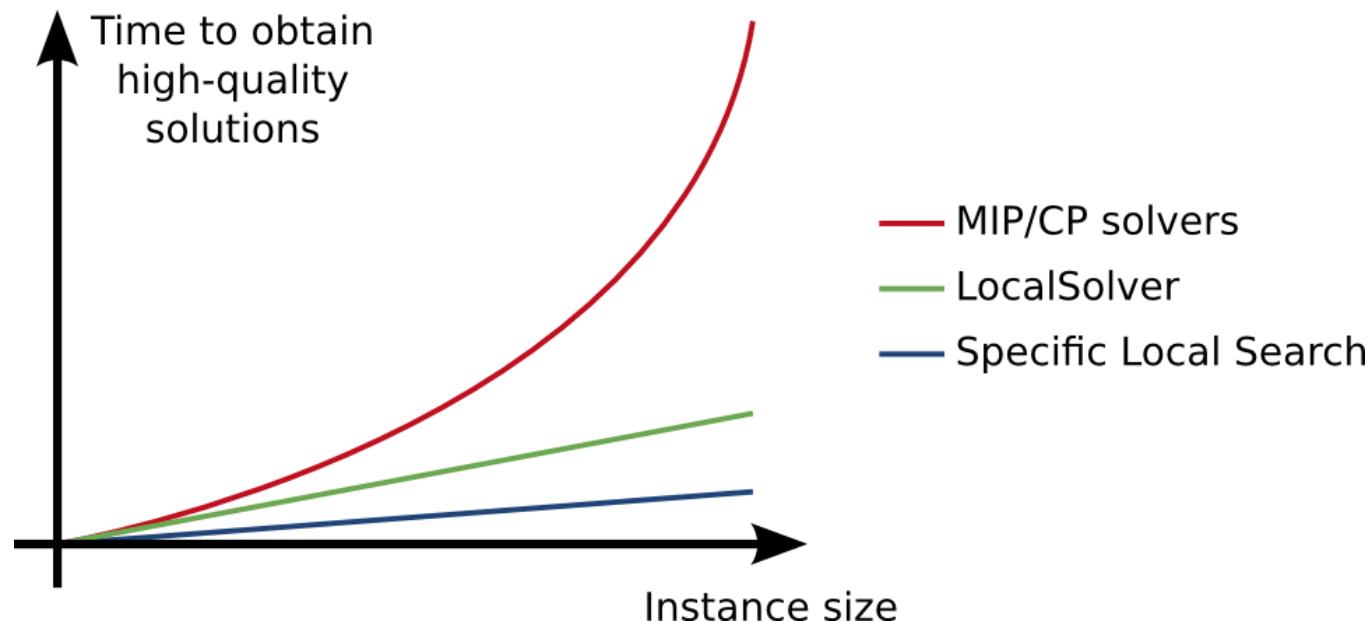

- Not suited to reach quickly good “integer feasible solutions”
- Designed to prove optimality
- Exponential time: not scalable (the best MIP solvers still fail to find feasible solutions for real-life instances with 10,000 binaries)

Benefits of local search

- Provides good-quality solutions in short running times
- Scalable (each iteration done in sublinear or even constant time)
- Able to optimize in nonconvex and nonsmooth spaces

Why local search?

LocalSolver

Quick tour

LocalSolver

Knapsack

8 items to pack in a sack: maximize the total value of items while not exceeding a total weight of 102 kg

```
function model() {  
    // 0-1 decisions  
    x_0 <- bool(); x_1 <- bool(); x_2 <- bool(); x_3 <- bool();  
    x_4 <- bool(); x_5 <- bool(); x_6 <- bool(); x_7 <- bool();  
  
    // weight constraint  
    knapsackWeight <- 10*x_0+ 60*x_1+ 30*x_2+ 40*x_3+ 30*x_4+ 20*x_5+ 20*x_6+ 2*x_7;  
    constraint knapsackWeight <= 102;  
  
    // maximize value  
    knapsackValue <- 1*x_0+ 10*x_1+ 15*x_2+ 40*x_3+ 60*x_4+ 90*x_5+ 100*x_6+ 15*x_7;  
    maximize knapsackValue;  
}
```

Binary decision variables

Integer intermediate variables

The user writes the model: nothing else to do!
declarative approach = model & run

Multiobjective knapsack

```
function model() {  
    // 0-1 decisions  
    x[0..7] <- bool();  
  
    // weight constraint  
    knapsackWeight <- 10*x[0]+ 60*x[1]+ 30*x[2]+ 40*x[3]+ 30*x[4]+ 20*x[5]+ 20*x[6]+ 2*x[7];  
    constraint knapsackWeight <= 102;  
  
    // maximize value  
    knapsackValue <- 1*x[0]+ 10*x[1]+ 15*x[2]+ 40*x[3]+ 60*x[4]+ 90*x[5]+ 100*x[6]+ 15*x[7];  
    maximize knapsackValue;  
  
    // secondary objective: minimize product of minimum and maximum values  
    knapsackMinValue <- min[i in 0..7](x[i] ? values[i] : 1000);  
    knapsackMaxValue <- max[i in 0..7](x[i] ? values[i] : 0);  
    knapsackProduct <- knapsackMinValue * knapsackMaxValue;  
    minimize knapsackProduct;  
}
```

Nonlinear operators: prod, min, max,
and, or, if-then-else, ...

Lexicographic objectives

Mathematical operators

Arithmetic		Logical	Relational
sum	prod	not	==
min	max	and	!=
div	mod	or	\leq
abs	dist	xor	\geq
sqrt	log	if	$<$
			$>$

Modeling language

```
function model() {  
    // 0-1 decisions  
    x[1..n] = 0;  
  
    // weights  
    knapsackWeight <- 0;  
    constraints:  
        // maximize knapsackValue  
        knapsackValue <- 0;  
        maximize knapsackValue;  
    }  
}
```

```
#include "localsolver.h"  
  
using namespace localsolver;  
  
int main()  
{  
    int weight[8];  
    int value[8];  
  
    LocalSolver lsolver;  
    LSModel* model = lsolver.CreateModel();  
  
    // 0-1 decisions  
    LSEExpression* x[8];  
    for (int i = 0; i < 8; i++)  
        x[i] = model.CreateExpression(LSOperator.Bool);  
  
    // knapsack weight  
    LSEExpression* knapsackWeight = model.CreateExpression(LSOperator.Sum);  
    for (int i = 0; i < 8; i++)  
        knapsackWeight.AddOperand(model.CreateExpression(LSOperator.Prod, weight[i], x[i]));  
  
    // knapsack weight constraint  
    model.AddConstraint(knapsackWeight, 102);  
  
    // knapsack value  
    LSEExpression* knapsackValue = model.CreateExpression(LSOperator.Sum);  
    for (int i = 0; i < 8; i++)  
        knapsackValue.AddOperand(model.CreateExpression(LSOperator.Prod, value[i], x[i]));  
  
    // maximize knapsack value  
    model.AddObjective(knapsackValue, LSObjectiveDirection.Maximize);  
  
    // close the model before solving it  
    model.Close();  
    LSPhase phase = lsolver.CreatePhase();  
    phase.SetTimeLimit(1);  
    lsolver.Solve();  
}
```

C++

```
import localsolver.*;  
  
public class Toy {  
    public static void Main()  
    {  
        int[] weights = {10, 60, 30, 40, 30, 20, 20, 2};  
        int[] values = {1, 10, 15, 40, 60, 90, 100, 15};

Real-life applications

Car sequencing

Scheduling cars along an assembly line

- Each car requires some options
- Each option induces a ratio constraint P/Q
- A class is a set of cars requiring the same options

Objective: to space options over the line

- We wish no more than 2 sunroofs over 5 consecutive cars
- For any window of 5 cars, a penalty is computed as $\max(n-2, 0)$ with n the number of cars requiring a sunroof

LSP model

$x_{cp} = 1 \Leftrightarrow \text{car of class } c \text{ is in position } p$

```
x[1..nbClasses][1..nbPositions] <- bool();  
  
for [c in 1..nbClasses]  
    constraint sum[p in 1..nbPositions](x[c][p]) == card[c];  
  
for [p in 1..nbPositions]  
    constraint sum[c in 1..nbClasses](x[c][p]) == 1;  
  
op[o in 1..nbOptions][p in 1..nbPositions] <- or[c in 1..nbClasses : options[c][o]](x[c][p]);  
  
nbVehicles[o in 1..nbOptions][j in 1..nbPositions-Q[o]+1] <- sum[k in 1..Q[o]](op[o][j+k-1]);  
  
violations[o in 1..nbOptions][j in 1..nbPositions-Q[o]+1] <- max(nbVehicles[o][j] - P[o], 0);  
  
obj <- sum[o in 1..nbOptions][p in 1..nbPositions-Q[o]+1](violations[o][p]);  
minimize obj;
```

Car sequencing at Renault

Additional constraints: no more than 10 consecutive cars with the same color

```
color[p in 1..nbPositions] <- sum[c in 1..nbClasses](color[c] * x[c][p]);  
same[p in 2..nbPositions] <- color[p] == color[p-1];  
toolong[p in 11..nbPositions] <- and[j in p-10..p](same[j]);  
for [p in 11..nbPositions] constraint not(toolong[p]);
```

Decision variables
remain the same

Additional objective: minimize the number of paint color changes

```
minimize sum[i in 2..nbPositions](not(same[i]));
```

Problem posed by Renault as 2005 ROADEF Challenge
LocalSolver competitive with finalists (ranked 16/55)

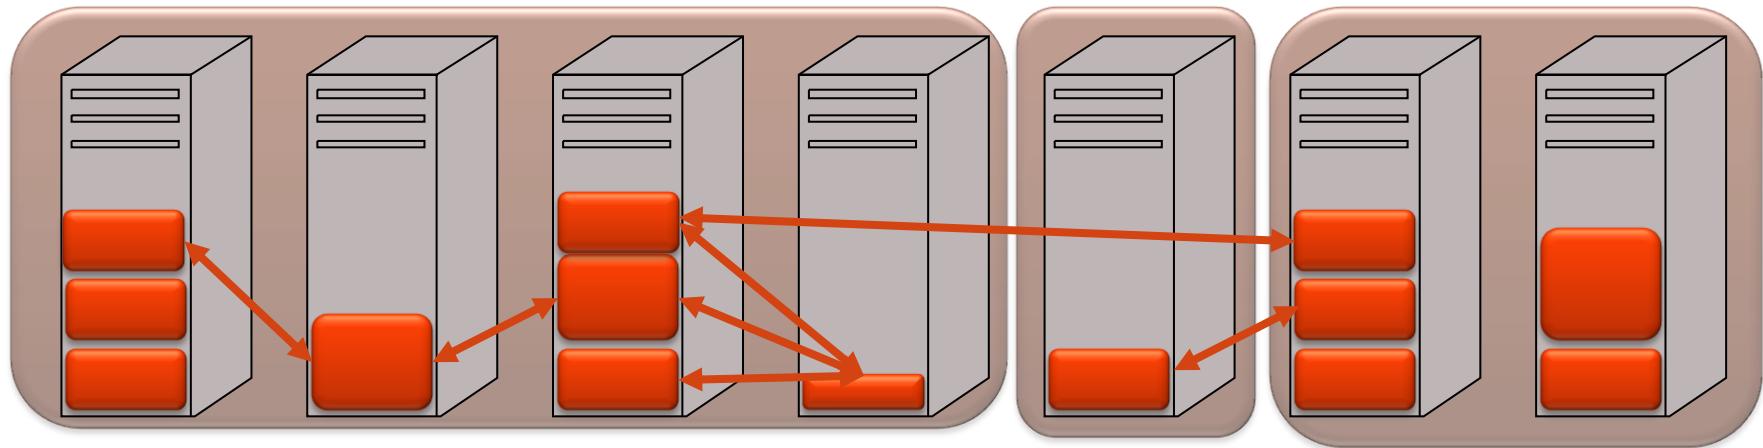

2012 ROADEF Challenge

EURO

Reassignment of processes to machines, with different kinds of constraints (mutual exclusion, resources, etc.)

More than 100 000 binary decisions

Only 1 day of work

LocalSolver qualified for final round (ranked 25/80)
